1. INTRODUCTION

The international aerospace sector has increasingly used in recent years unmanned aerial vehicles (UAV - Unmanned Aerial Vehicle) for missions of various types, such as: aerial photography, military reconnaissance, atmospheric research at high altitude, radio communication, surveillance, fire detection, technology development, etc.. Despite the technology involved, UAVs have dimensions smaller than manned aircraft, making their operation more flexible and more economical. The increasing automation and communication capabilities and the evolution of available materials has allowed the operation of these aircraft at distances and altitudes greater than ever, increasing their potential by making them equal, or even superior, to other aircraft that need to carry on board systems for crew support. For short distance surveillance applications, the investment required for the development and operation of a UAV is comparatively lower than equivalent manned aircraft so that its use in these tasks results in a cost-benefit ratio much more attractive. The UAV sector is the only sector of the aerospace industry with significant growth in the last 30 years, with an average growth rate of over 14% per year.

The UAV sector is rapidly flourishing and in many cases it is a source of concepts and technologies for manned aircraft. Currently, most UAVs in operation have military applications. The use of UAVs in civil applications is, however, growing rapidly with the appearance of new concepts of operation and the creation and maturation of appropriate legislation. Portugal needs to stay in this important aerospace area in order to be more autonomous in the development of technological means essential to the sustainability of its resources and its regional and national economic maturity, to employ its qualified manpower and to be a competitive exporter of technology.

Portugal also needs the use of UAVs in various areas of activity. Monitoring of forest areas which in recent years have succumbed to fires is an important example. The application of surveillance unmanned aerial vehicles allows a high degree of uptime and availability in the tasks of this nature and is a complementary means of ground surveillance and satellite monitoring already in use. The application of new UAV concepts to new civil scenarios that can be economic viable is also important.

In the past few years electric propulsion for aircraft has seen tremendous developments and a widespread use. Its application ranges from the model aircraft, UAVs, sailplanes and ultralight aircraft. Because batteries have a limited energy density, resulting in flights of short duration, the use of fuel cells for battery charging is an interesting option that has already been exploited. Conventional propulsion with a piston engine allows flights with longer duration and with the help of an alternator coupled to the engine batteries, that provide on-board power for systems, can be recharged in flight. To avoid consumption of gasoline to produce electricity the incorporation of photovoltaic cells on the aircraft can provide part or all of the electrical energy required on board. In some situations an hybrid propulsion system may be preferred.

The main objective of this subject is to show students what the conceptual design of an aircraft is and what steps are necessary to follow given mission and performance requirements, design constraints, design methods and the need for optimization. To achieve this, the knowledge gained will be applied to the design of a new aircraft subjected to specific requirements. The optimization of the project is of extreme importance in the development of a new aircraft.

This project description gives the requirements that the aircraft must respond to in terms of mission, configuration, performance, systems, materials and design standards. It also

describes the necessary tasks to be performed during the semester and the work plan to follow. This project requires dedication and continuous work to ensure that deadlines are met and results lead to a good design.

2. REQUIREMENTS

The current requirements follow a need for a flexible and multitasking UAV able to perform efficient horizontal flight and also to perform vertical landing, take-off and hover. The requirements for this aircraft are listed below and during the course of the project they must be respected. Possible changes in the requirements will be discussed and agreed upon by the teacher and all the elements involved in the project.

It is required to perform the conceptual and preliminary design of a UAV taking into account some specific design requirements. The aircraft must have good flying qualities to allow easy and precise flying. The vehicle's structure and aerodynamics must be carefully designed to achieve low power consumption levels. Simplicity, robustness and ease of repair are essential to maintain high levels of operational readiness of the UAV.

2.1. Mission

The UAV must be designed for the following mission: it must take off vertically from a small yard or roof top by its own means, then reconfigure from vertical flight to horizontal flight and climb to an altitude of 500 m, cruise for 50 km to the destination point, descend, land vertically and drop a small package; then take off vertically again, cruise back to base and land vertically on the same yard or roof top.

2.2. Performance

The vehicle must show the following performance figures (ISA conditions):

Take-off vertical
Cruise speed above 100 km/h
Maximum speed at least 125 km/h
Flight operational radius 50 km
Data link range at least 50 km
Service ceiling 500 m
Landing vertical

2.3. Propulsion

Electric motors and/or piston engines may be selected for this UAV. The possibility of using a hybrid propulsion system should be considered for improved flexibility and increased range. The propellers must be selected according to the motor/engine performance and UAV performance required both in vertical and horizontal flight. The aircraft can either have tractor or pusher propellers and can have as many propulsion units as required. In selecting the motor/engine, careful attention must be given to its durability and reliability. Proper cooling of the motor/engine must be provided. Tilting of the motors/engines may be required to fulfil the operational needs.

2.4. Wings

The wings must be well designed, both aerodynamically and structurally, so that the overall efficiency of the vehicle is high and allow the required mission to be accomplished with low energy requirements. According to the mission, the wings must be designed for transition and high speed flight and have high lift-to-drag ratio. The structure should use high specific strength and high specific stiffness materials to allow for an empty weight as low as possible. A tilting wing may be considered in conjunction with the tilting motors/engines.

2.5. Fuselage

The fuselage should be slender and light, yet possessing the necessary internal space for systems and payload. It should have high tolerance on payload weight and position. Equipment substitution and payload access should be quick and simple to perform with access from the bottom and top of the fuselage. The payload compartment should be capable of carrying a small package which must be automatically delivered / dropped by means of rotating or swivelling doors on the destination site. The payload compartment should have the reference dimensions 320 mm x 220 mm x 120 mm.

2.6. Tail

The tail must be small and effective. It should use in their structure the same materials selected for the wings.

2.7. Landing Gear

The UAV-16 must have a rugged but simple landing gear. The use of a retractable gear may be used but it should only be selected if the overall performance of the UAV is improved over a fixed one.

2.8. Payload

All electronic and electric components and mission equipment must be placed within the fuselage according to their function and in such a way as to allow its quick preparation or replacement. The payload (up to 2 kg) must be well secured in the fuselage to avoid any movement during flight. Provision for a door is required to drop the payload.

2.9. Weight and Balance

The centre of gravity (CG) travel must be such that no negative impact on the stability or on the normal operation of the UAV is imposed for any payload weight. The maximum take-off mass of the UAV should not exceed $10\,\mathrm{kg}$.

2.10. Controls and Systems

The control system will include autopilot boards (or at least physical space for those) which are not required to be selected. Control surfaces, tilting surfaces and motor/engine's tilting mechanisms must be sized and actuated by servomotors. The electric system should be powered by batteries which are charged by an alternator driven by the engine in the hybrid propulsion configuration.

2.11. Design Airworthiness Requirements

The design airworthiness requirements that should be used in the structural sizing are the EASA CS-VLA or CS-23. The design manoeuvre limit load factors are, in principle, +3 and -1.5, but those should be checked with a n-V diagram. All work performed in the design should aim at achieving high levels of safety and performance.

3. TASKS

There are several tasks in the design project that must be carried out according to the time plan below. All tasks depend on each other so that there must be a close interaction and updating between them. The design process is also iterative in nature but perfection is not possible nor is necessary but an effort must be put forward to achieve a good optimization level in the outcome.

The necessary calculations may be performed with the help of spread sheets and also other analysis computer programs. All drawings should be, preferably, done in CATIA V5.

3.1. Layout

The layout and functionalities of the vehicle must be selected so that the requirements are fully met. This task is very important because it integrates all needs of the other parts of the project into a viable configuration. A preliminary three dimensional (3D) study of all major components must be performed and these must be incorporated in the aircraft structure. 3D drawings must be produced in a CAD system for the complete UAV.

3.2. Aerodynamics and Stability

The aerodynamic study must cover the selection of the aerofoils, geometry and size of the lifting surfaces, nacelles and the computation of the aerodynamic characteristics of the whole vehicle (C_L , C_D e C_M). It must be assured that all choices made in the overall design do not impair the aerodynamic performance. A study of the stability and control of the UAV must also be performed.

The aerodynamic work must concentrate on the wings design. These must be optimized having in mind the necessary compromises for different flight conditions.

3.3. Propulsion and Performance

The propulsive system (motor, propeller, power source, fuel system) must be selected and sized according to the requirements. An estimate of the vehicle's performance (speeds, times, fuel usage, etc.) must be carried out.

3.4. Systems

A study of the landing gear system, of the control system and of the electric system must be performed. These studies should include not only the selection of the main components and definition of its functionalities but also the positioning of components and routing of cables inside the aircraft. Commercially available components are preferred to

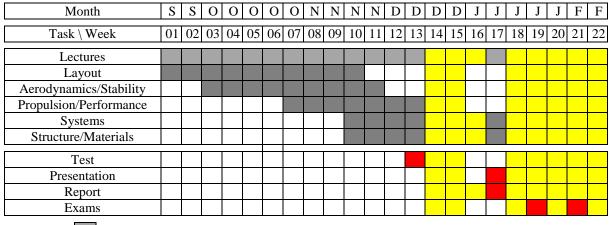

speed up both design and building processes. A database containing such data as suppliers, working characteristics, weight and price of all components selected must be produced.

3.5. Structure and Materials

The type of structure and materials for the different parts of the vehicle must be selected and defined adequately keeping in mind their configuration and function. Preliminary sizing of the wing must be performed. A database containing such data as suppliers, physical characteristics, mechanical characteristics and price of all materials selected must be produced. A study on the manufacturing processes to be used must be carried out together with estimates of weight and balance and total cost of the UAV.

3.6. Time plan

The table below presents the time plan with the tasks required to complete de project.

Legend: Lectures
Design work
Weeks without lectures
Assessment

3.7. Work Requirements

The design is carried out by groups of 5 students. In order for the project objectives to be fulfilled in time all students should work hard.

4. ASSESSMENT

The grade of this subject is given based on one written test (T), one oral presentation (P) and one report (R).

4.1. Test

The test covers all the topics discussed during classes up to the date of the test (12 December 2016 – week 13). The test is divided into two parts: the first is closed book and the second is open book.

4.2. Presentation

Near the end of the semester there will be an oral presentation of the project (9 January 2017 – week 17). In the presentation, when the project is almost complete, each design team (all elements of the team must participate in the presentation) must show to the other teams that their design meets all requirements and explain the steps that led to the final concept. This presentation should take 20-30 minutes for each team, depending on the number of teams that exist.

4.3. Report

Each team must write up a design report that should contain all relevant steps taken in the UAV design process, including layout, decisions made, major calculations, results, etc.. Sketches necessary to fully understand the design and a three view drawing with all major dimensions and aircraft characteristics should also be included. The number of pages is limited to around 30, using letter size 12 and single line spacing. The report should be handed in *pdf* format at the last day of lectures together with the original CAD drawings (13 January 2017 – week 17).

4.4. Exam

There will be no written exam. If students fail the "Frequência" assessment or wish to improve their final grade, they must hand in an improved report of their design project at the dates of the exam, in weeks 19 or 21.

4.5. Grade

The mark of this subject is given by F = 0.3T + 0.2A + 0.5R and approval is obtained if $F \ge 10$. The same is true for the exam final mark.

| 1. | | Frequência (F = $0.3T + 0.2A + 0.5R$) | | 100 |
|----|----|--|--------------------|-----|
| , | T | Test | 12-12-2016 (09h00) | 30 |
| | A | Presentation | 09-01-2017 (09h00) | 20 |
| | R | Report | 13-01-2017 (24h00) | 50 |
| | | | | |
| 2. | | Exam $(E = 0.3T + 0.2A + 0.5 R1)$ | | 100 |
| | R1 | Report (normal period) | ??-01-2017 (??h30) | 50 |
| | R1 | Report (recourse period) | ??-02-2017 (??h30) | 50 |
| | | | | |
| 4. | | Exam $(E = 0.3T + 0.2A + 0.5 R2)$ | | 100 |
| | R2 | Report (special period) | ??-07-2017 (??h00) | 50 |

5. REFERENCES

The books listed below can be used for the design. The design reports of previous years may also be useful as general guideline and source of ideas. However one must bear in mind that the information contained in them may be incorrect. A lot of information can also be found in the internet using appropriate search criteria.
